Bleeding manifestations in dengue and their correlation with the platelet count

*B Sreenivasa¹, B Manjunatha², Joseph Nivil³

Abstract

Objective: To study the common bleeding manifestations in dengue and see whether there is a correlation between them and platelet counts less than 100,000/cu.mm.

Method: Children below the age of 14 years with dengue seropositivity were included in the study. Relevant blood investigations were done and patients were managed according to World Health Organisation guidelines.

Results: A total of 100 children with a mean age of 7.9 ± 3.7 years were included in the study. During the course of illness, bleeding occurred in 60% of children. It was found that 26% of children had melaena, 20% had petechiae, 8% had haematemesis, 4% had epistaxis and 2% had gum bleeding. All (100%) the patients who had platelet counts between 50,001-100,000/cu.mm developed haemorrhage and 95.8% of patients with platelet range between 20,001-50,000/cu.mm of blood had developed haemorrhage. However, of patients who had platelet counts less than 20,000/cu.mm, 41.8% developed haemorrhage and 58.2% did not have haemorrhagic manifestations (p =0.001).

Conclusions: No correlation was found between platelet counts <100,000/cu mm and increase in incidence of bleeding manifestations in DHF.

(Key words: Dengue haemorrhagic fever, bleeding, platelet count, thrombocytopenia, coagulation).

Introduction

Dengue is an arboviral infection transmitted through the bite of the Aedes mosquito¹. In developing countries epidemics are becoming more frequent straining the limited resources of the public health system¹. Many dengue fever cases are self-limiting, but the complications, such as haemorrhage and shock can be life threatening². Dengue haemorrhagic fever (DHF) ranks high among the newly emerging infectious diseases of public health significance and is the most important of the arthropod borne viral diseases³. Approximately 2.5 billion people live in dengue-risk regions with about 100 million new cases each year worldwide⁴.

Objective

To study common bleeding manifestations in DHF and see whether there is a correlation between them and platelet counts less than 100,000/cu.mm.

Method

A prospective observational study was conducted in Basaveshwara Medical College Hospital, Chitradurga from April to August 2016 on children less than 14 years of age who were seropositive for dengue. The inclusion criteria were as follows:

- Seropositivity for any one or all of NS1Ag, IgM and IgG antibodies for dengue.
- An acute febrile illness lasting for 2-7 days, with any one or more of the following:
  - Myalgia
  - Headache
  - Retro-orbital pain
  - Vomiting
  - Abdominal pain
  - Hepatomegaly
  - Jaundice
  - Seizures
  - Spontaneous bleeding manifestations
  - Thrombocytopenia with platelet counts less than 100,000/cu.mm, or evidence of plasma leakage i.e. pleural effusion, ascites or hypoproteinaemia, with or without signs of circulatory failure.

The exclusion criteria were as follows:

- All subjects seronegative for NS1Ag, IgM and IgG antibodies for dengue.
- Subjects with a history of bleeding disorders of other aetiology such as
immune thrombocytopenic purpura, haemophilia etc.

The first 100 seropositive children who fulfilled the inclusion criteria were included in the study. Detailed demographic data, clinical history, physical examination findings and relevant baseline investigations (haemoglobin level, total leucocyte and differential count, platelet count, packed cell volume) were recorded as per pre-designed proforma. The children were managed as per World Health Organisation (WHO) guidelines. The cases were followed-up daily for the clinical and laboratory parameters till they were discharged. Haemoglobin level, platelet count and packed cell volume were done at least once per day and at more frequent intervals in children admitted to the paediatric intensive care unit (PICU). Prothrombin time (PT), activated partial thromboplastin time (APTT), international normalised ratio (INR), aspartate aminotransferase (AST), alanine aminotransferase (ALT) and serum albumin were done as and when needed. Chest x-ray and ultrasonogram (USG) of abdomen were done to see capillary leak whenever needed. Widal test, test for malaria parasite, blood urea, serum creatinine, etc. were done when the clinical history and symptoms prompted us to do the same for diagnosis and management.

Descriptive statistics were used. Chi-square test was done to find out the association between two attributes using SPSS for windows (version 16.0). p<0.05 was considered statistically significant.

Results
A total of 100 serologically positive dengue cases, with mean age of 7.9 ± 3.7 years, were included in the study. Males were 53% and females 47%. Other than fever, which was present in all cases, the most common presenting complaints were vomiting (26%), headache (10%), black coloured stool (6%) and bleeding (5%). During the course of the illness, bleeding occurred in 60% of the children. Whilst 26% had melaena, 20% had petechiae, 8% had haematemesis, 4% had epistaxis and 2% had gum bleeding. None of the children with bleeding had received non-steroidal anti-inflammatory drugs (NSAIDS).

Among the bleeding children, mean AST was 128.6 IU/L (normal 1-55 IU/L), mean ALT 40.2 IU/L (normal 5-45 IU/L), mean PT 20.396 ± 16.269 seconds (normal range 13.5 to 100 seconds), mean APTT 40 ± 13.7 seconds (normal range 30.8 to 100 seconds) and the mean INR was 2.65. Signs of capillary leak were observed in 69% of children and 11% had experienced shock. Whilst 20% and 18% of patients respectively developed signs of capillary leak on day 4 and day 5 of illness, 13% developed signs of capillary leak on day 6 of illness. Range of onset of capillary leak was between 2nd and 8th day (Mean=4.7).

A comparison of the mean haemoglobin, PCV and platelet counts on admission and during bleeding is shown in Table 1.

Table 1: Comparison of mean haemoglobin, PCV and platelet counts on admission and during bleeding

<table>

<tr>
<td>Platelet count (per cu mm)</td>
<td>41,861.6</td>
<td>17,198</td>
<td>0.0001</td>
</tr>
</tbody>
</table>

There was a statistically significant fall in haemoglobin, PCV and platelet count during bleeding (Table 1).

Among the 100 children studied 24% had leucopenia, 17% had leucocytosis and 59% had normal leucocyte counts. Of the 100 children, 41 had dengue serology suggestive of primary dengue and 59 had dengue serology suggestive of secondary dengue. Of the children with primary dengue 24 (58.5%) had bleeding manifestations predominantly petechiae, whereas 36 (61%) of the children with secondary dengue had bleeding manifestations predominantly melaena and haematemesis. Two children died, both cases of secondary dengue.

The relationship between dengue shock and platelet counts is shown in Table 2.

Table 2: Relationship between shock and platelet counts

</table>
Of the 11 patients with dengue shock, 15.6% had platelet counts from 50,001–100,000 per cu mm, 9.3% had platelet counts from 20,000-50,000 per cu mm and 8% had platelet counts less than 20,000 per cu mm. The relationship between shock and platelet counts was not statistically significant.

The relationship between dengue haemorrhage and platelet counts is shown in Table 3.

### Table 3: Relationship between haemorrhage and platelet counts during course of illness

All the patients who had platelet counts between 50,001-100,000/cu.mm developed haemorrhage and 95.8% of patients with platelet counts between 20,000-50,000/cu.mm developed haemorrhage. However, of the 67 patients who had platelet counts less than 20,000/cu.mm, 41.8% developed haemorrhage whilst 58.2% did not. This is statistically significant. (P =0.001; p<0.01).

The relationship between the bleeding pattern and platelet counts during the course of illness is shown in Table 4.

</table>

Among patients with bleeding manifestations, 53.3% patients had hepatomegaly, (26.6%) being in patients who had platelet counts <20,000 per cu mm. Among patients without bleeding manifestations, 40% patients had hepatomegaly, 37.5% being in patients who had platelet counts less than 20,000 per cu mm. This was not statistically significant.

In our study of 100 children of DHF, NS1 Ag was positive only in 28% of cases, NS1 Ag and IgM was positive in 12%, IgM only was positive in 1%, IgM and IgG was positive in 25%, NS1 Ag, IgM, IgG was positive in 15%, NS1 Ag, IgG was positive in 8%, IgG was positive only in 11% of cases.

In our study bleeding occurred in 60% of patients, 34% having gastrointestinal (GI) bleeding (26% melaena, 8% haematemesis), 20% having petechiae, 4% having epistaxis and 2% having gum bleeding. Our study is similar to that of Ahmed MM, who found haematemesis in 19%, gum bleeds in 16%, epistaxis in 12%, melaena in 8% and subconjunctival haemorrhage in 4%. It is also similar to a study by Ratageri et al. where GI bleeds were seen in 22% and petechiae in 18%. However, a study done by Kishore et al. showed haemorrhage into skin (purpura, petechiae or ecchymoses) as the commonest manifestation of bleeding (17%).

In our study platelet counts less than 100,000 per cu mm were present in all dengue patients. A study by Kulkarni et al., revealed thrombocytopenia in 84% of children with dengue and a study by Ahmed MM revealed thrombocytopenia was seen in 68.5% dengue patients. However, in a study by Banerjee et al., thrombocytopenia was seen in only 19% dengue patients. In our study, 9% of patients had platelet counts between 50,000-100,000 /cu. mm, 24% had platelet counts between 20,000-50,000 /cu.mm and 67% had platelet counts less than 20,000 /cu.mm. In a study by Malavige et al., 24.2% had platelet counts between 50,000-100,000/cu mm, 46% had platelet counts between 20,000-50,000/cu mm and 30% had platelet counts less than 20,000 /cu.mm. In a study by Kamath et al., 62.3% had platelet counts less than 50,000/cu.mm.
In our study whilst 100% patients who had platelet count between 50,001-100,000/cu.mm developed haemorrhage and 95.8% patients with platelet counts between 20,000-50,000/cu.mm developed haemorrhage, only 41.8% patients who had platelet counts less than 20,000/cu.mm developed haemorrhages. Our observations were similar those of Joshi et al., Sunil Gomber et al., and Dhooria et al. who also found poor correlation between thrombocytopenia and bleeding manifestations. No correlation was found between reducing trend of platelet count and increase in incidence of bleeding manifestations indicating that abnormal platelet aggregation or disseminated intravascular coagulation may have a role in bleeding in DHF cases rather than reduction in absolute numbers as the cause of bleeding manifestations. However, a study by Narayanan et al., showed that bleeding has a correlation to platelet count only when it is less than 50,000/cu.mm of blood.

Conclusions
- In 58.5% children with primary dengue, petechiae, epistaxis, gingival bleeding were the common bleeding manifestations whereas in 61% children with secondary dengue melaena and haematemesis were the common bleeding manifestations.
- There was no correlation between platelet counts below 20,000 per cu mm and bleeding manifestations.
